

# Rare Diseases of Bone Development

Disease	Overview	Signs and Symptoms	Gene Defect	Underlying Impairment	Diagnostics	Treatment
<b>Hypophosphatasia (HPP)</b>	Metabolic disorder causing impaired bone mineralization	<ul style="list-style-type: none"> <li>• Soft, fragile bones that fracture easily and heal slowly</li> <li>• Bowed legs/ other skeletal deformities</li> <li>• Premature loss of primary teeth</li> </ul>	Mutations in ALPL (also called TNSALP) gene	Inability to manufacture alkaline phosphatase (ALP) enzyme needed for bone development	<ul style="list-style-type: none"> <li>• Bone x-rays</li> <li>• Lab tests for serum ALP (low)</li> <li>• Lab tests for vitamin B-6 (high)</li> <li>• Gene testing</li> </ul>	Enzyme-replacement therapy called asfotase alfa (Strensiq™)
<b>Osteogenesis imperfecta (OI)</b>	Connective-tissue disorders resulting in fragile, brittle bones that can fracture upon minimal trauma	<ul style="list-style-type: none"> <li>• Frequent broken bones in infancy, puberty, and late adulthood</li> <li>• Bone deformity</li> <li>• Short stature</li> </ul>	Mutations in COL1A1 or COL1A2 genes	Impairment of quality or quantity of type 1 collagen, a protein needed for healthy bone, cartilage, tendons	<ul style="list-style-type: none"> <li>• Gene tests</li> <li>• Bone x-rays</li> <li>• DXA scan</li> <li>• Prenatal ultrasound for severe forms</li> </ul>	<ul style="list-style-type: none"> <li>• Lifestyle to minimize fractures</li> <li>• Surgery</li> <li>• Physical therapy</li> <li>• Off-label use of bisphosphonates, growth hormone</li> <li>• Investigational drugs</li> </ul>
<b>Familial Hypophosphatemia (XLH)</b>	Metabolic disorder that affects bone mineralization through an impairment that leads to low levels of phosphate and vitamin-D	<ul style="list-style-type: none"> <li>• Bowed legs (congenital rickets)</li> <li>• Concave chest</li> <li>• Short stature</li> <li>• Progressive bone-softening</li> <li>• Long head shape</li> <li>• Tooth abscesses</li> <li>• Late teeth</li> </ul>	Mutations of the PHEX gene, located on the X chromosome, in most cases; inherited as a dominant gene and thus can affect both sexes	Impaired phosphate transport to cells; impaired vitamin D metabolism in kidneys	<ul style="list-style-type: none"> <li>• Lab tests for serum phosphate, magnesium, calcium, and potassium</li> <li>• 24-hour urine phosphate excretion</li> <li>• Bone x-rays</li> <li>• Genetic tests</li> </ul>	<ul style="list-style-type: none"> <li>• Nutritional supplements</li> <li>• Supportive measures for pain and mobility</li> <li>• Tooth sealants</li> <li>• Surgery</li> </ul>
<b>Hereditary Hyperphosphatasia</b>	Very rare bone disorder that causes progressive skeletal malformations, mostly in long bones of arms and legs.	<ul style="list-style-type: none"> <li>• Widened/bowed arm/leg bones</li> <li>• Thickened long bones</li> <li>• Difficulty walking</li> <li>• Short stature</li> <li>• Thickened upper skull</li> </ul>	Mutations of the TNFRSF11B gene, in about 2/3 of cases.	Rapid bone turnover resulting from deficiency of the osteoprotegerin protein.	<ul style="list-style-type: none"> <li>• Bone X-rays</li> <li>• Lab test for serum alkaline phosphatase</li> <li>• Urine tests for markers of bone turnover</li> </ul>	<ul style="list-style-type: none"> <li>• Supportive, symptomatic</li> <li>• Off-label bisphosphonates</li> <li>• Investigational drugs</li> </ul>
